1. FEATURES

(1) High transmission efficiency

Sankyo ball screws have an extremely high transmission efficiency of over 90%, as compared with the conventional Acme screws, and the required torque reduced to only one-third or less. This allows the effective conversion of linear motion to rotary motion. (See Chart on the next right.)

(2) Axial clearance adjustable

Conventional Acme screws do not roll smoothly when the axial clearance is small. Sankyo ball screws, however, can roll smoothly even when the axial clearance is reduced.

In addition, Sankyo ball screws can eliminate the axial clearance by preloading with two nuts and also resulting in increased rigidity.

(3) Long life and low wear

Due to rolling contact, very little wear occurs over the life of the ball screws, assuring high precision performance for long period of time.

(4) Precision fine feed possible

Reduced starting torque due to the rolling contact permits precision fine feed.

(5) High precision

All Sankyo ball screws are ground, assembled and inspected under a strict temperature control.

(6) Drastic quality control system

Sankyo has promptly obtained a qualification for ISO9001 and established a drastic quality control system to manufacture quality products that can satisfy customers' needs to the full.

2. ACCURACY

2.1 Accuracy Grade

The grade of accuracy of Sankyo Precision Ball Screws conformes to JIS B 1192 (Ball Screws) and is prescribed by JIS Series (C0, C1, C3, C5) and (G1, G3, G5) conforming to ISO.

2.2 Lead Accuracy

Lead Accuracy for Sankyo Precision Ball Screws conforms to JIS B 1192 (Ball Screws) which prescribes the tolerance on specified travel and travel variation in respect to the effective length of threaded portion of screw shaft, as well as on travel variation in respect to a length of 300mm taken arbitrarily within the effective length of the screw shaft and on travel variation in respect to arbitrary one revolution $(2\pi \text{ rad})$ within the effective length of threaded portion.

2.2.1 Terms and Definitions of Lead Accuracy

(1) Specified lead

Lead that is calculated by correcting the nominal lead to some degree to compensate the amount of deformation which may occur due to temperature rise or load.

(2) Specified travel r s

Axial travel attained when screw shaft has been rotated by arbitrary number of times in accordance with specified travel. [2] in Fig. 2]

(3) Actual travel r a

Axial travel obtained by continuous measurement of the actual axial travel of nut to arbitrary angle of screw shaft rotation. [③ in Fig.2]

(4) Actual mean travel r m

Straight line representing the tendency of actual travel. This straight line can be obtained by the least square method or a simple and appropriate approximation method similar to that, from a curve indicating the actual travel in respect to the effective travel of the nut or the effective length of threaded portion of the screw shaft. $[\textcircled]$ in Fig.2]

(5) Tolerance on specified travel ep

Difference between actual mean travel corresponding to the effective travel of the nut or the effective length of threaded portion of the screw shaft and specified travel. [⑤ in Fig.2]

(6) Travel variation v

The maximum width of actual travel curve put between 2 straight lines drawn in parallel to actual mean travel line, and it is specified on the following 3 items.

- vu :That corresponds to the effective travel distance of nut or effective length of threaded portion of the screw shaft. [6 in Fig.2]
 v300 :That corresponds to a length of 300mm which
- v300 :That corresponds to a length of 300mm which is arbitrarily taken within the effective threaded portion of the screw shaft. [⑦ in Fig.2]
- v2 π :That corresponds to one arbitrary revolution (2 π rad) within the effective threaded portion of screw shaft. [**(B)** in Fig.2]

(7) Target value C of specified travel

Target value used to preset specified travel to "minus" or "plus" side against nominal travel. [@in Fig.2]

2.4 Preload Torque

2.4.1. Terms and Definitions of Preload Torque

(1) Preload Fpr

A force which is allowed to exert action in a ball screw, assembling a group of nuts, which have been displaced in an axial direction to each other, to attempt to decrease the backlash and to increase the ridgidity of the ball screw.

(2) Dynamic drag torque T_p

A dynamic torque required to rotate the nut against the screw shaft or the screw shaft against the nut, under the conditions of the ball screw which has been subjected to the prescribed preload in the absence of any external load and with the end seal removed.

(3) Total dynamic drag torque Tr

A dynamic torque required to rotate the nut against the screw shaft or the screw shaft against the nut, under the conditions of the ball screw which has been subjected to the prescribed preload in the absence of any external load and with the end seal removed.

(4) Basic torque Tpo

Dynamic drag torque which has been established as a target. $[\circ{1}]$ in Fig. 3]

(5) Fluctuation value of basic torque ΔT_{P^0}

Fluctuation value of dynamic drag torque which has been established as a target. It is taken as the positive and negative in respect to basic torque. [2] in Fig. 3]

(6) Fluctuation rate of torque

Rate of basic torque fluctuation value ΔT_{po} to basic torque T_{po} .

(7) Actual torque curve

Dynamic torque curve which has been measured on actual preload ball screw. [3] in Fig. 3]

(8) Mean actual torque Tpa

Arithmetic mean value of maximum value and mininum value of actual torque (except starting torque) when measured allowing the nut to have reciprocating motion in respect to the effective length of the threaded portion. [④ in Fig. 3]

(9) Fluctuating value of actual torque ΔT_{Pa}

Maximum fluctuation value of actual torque curve (except starting torque) when measured allowing the nut to have reciprocating motion in respect to the effective length of threaded portion. It is taken as the positive and negative in respect to mean actual torque. [5] in Fig. 3]

(10) Fluctuation rate of actual torque

Rate of mean actual torque ΔT_{pa} to fluctuation value of actual torque T_{pa} .

Note (4) : Slenderness means the numerical value of effective length of threaded portion of the screw shaft divided by the nominal outside diameter of ball screw.

Remarks: Basic torque of not more than 0.2 is separately controlled by Sankyo Standard.

2.5 Accuracies on Supporting Part of Ball Screw

2.5.1 Accuracies on supporting part of C Series Ball Screws

Fig. 4 shows Accuracies on supporting part of ball screw. The respective accuracies and permissible values conform to JIS B 1192 (Ball Screws).

- (3) Squareness of end face of supporting part in respect to axial line of supporting part of screw shaft. (4) Squareness of basic end face of nut or flange mounting
- (1) Circumferential runouts in radial direction of outside diameter of the supporting part of screw shaft in respect to axial line of screw groove surface.
- (2) Circumferential runouts in radial direction of outside diameter of the mounting part in respect to axial line of supporting part of screw shaft.
- surface in respect to axial line of screw shaft. (5) Circumferential runout in radial direction on outer peripheral face of nut (in case of cylindrical shape) in respect to axial line of screw shaft.
- (6) Parallelism of outer peripheral face of nut (in case of plane mounting surface) in respect to axial line of screw shaft.
- (7) Total radial runout on axial line of screw shaft.

4.3 Supporting Method

Fig. 6 shows the typical method of supporting ball screws. When strict operating conditions of high degree of accuracy are required, careful consideration must be taken because the supporting method has a direct relation to permissible axial load and critical speed.

4. DESIGN OF SCREW SHAFTS

4.4 Permissible Axial Load

(1) Buckling load (Oblique lines in Fig. 7)

When the screw shaft is subject to compression load, it is necessary to take measures to prevent buckling in accordance with the following equation.

$$P = \frac{n \cdot \pi^2 \cdot E \cdot I}{Lz^2} \times a$$

Where P: Permissible axial load to buckling (N)

- a : Safety factor (0.5)
- Lz: Distance between loading points (mm) (See Fig. 6.)
- E: Modulus of longitudinal elasticity (2.06 x 10⁵N/mm²)
- I : Minimum secondary moment of screw shaft cross section (mm⁴)

$$I = \frac{\pi}{64} dr^4$$

1

dr: Screw shaft root diameter (mm) (See Dimension Table.)

| Factor determined by supporting me ball screws | thod of |
|--|---------|
| Both ends supported | n=1 |
| One end fixed other end supported | n=2 |
| Both ends fixed | n=4 |
| One end fixed other end free | n=0.25 |
| | |

(2) Permissible tensile compressive load (Perpendicular lines to permissible axial load scale marks) When the distance between loading points is short, it is necessary to examine permissible tensile compressive load in accordance with the following equation independently of the supporting method. Select a proper load on the "Both ends fixed" scale.

 $P = \sigma \cdot A$

Where P : Permissible tensile compressive load (N)

- σ : Permissible stress (147N/mm²)
- A : Sectional area at screw shaft root diameter (mm²)

$$A = \frac{\pi}{4} dr^2$$

dr : Screw shaft root diameter (mm) (See Dimension Table.)

(3) Parallel lines to the permissible axial load scale marks represent the maximum length of screw shafts that can be manufactured in the standard operation for the nominal screw shaft outside diameter. As the screw shaft length is limited by the grade, refer to Fig. 5 (Page 8).

-10 -

4.5 Permissible Operating Speed

(1) Critical speed (Oblique lines in Fig. 8)

It is necessary to examine critical speed so that the number of revolutions of the ball screw may not resonate with the natural frequency of the screw shaft.

$$N = \frac{60 \lambda^2}{2 \pi \cdot Lc^2} \sqrt{\frac{E \cdot I \cdot g}{\gamma \cdot A}} \times a$$

Where N : Permissible operating speed for critical speed (rpm)

- α : Safety factor (0.8)
- Le: Distance between supports (mm)
- (See Fig. 6.) Modulus of longitudinal elasticity E : (2.06 x 10^sN/mm²)

I : Minimum secondary moment of screw shaft cross section (mm4)

$$I = \frac{\pi}{64} dr^4$$

- Screw shaft root diameter (mm) dr : (See Dimension Table.)
- Acceleration of gravity g :
- (9.8 x 103mm/sec2)
- Specific gravity $(7.7 \times 10^{-5} \text{N/mm}^3)$ Á: Sectional area at screw shaft roof diameter
- (mm^2)

$$A = \frac{\pi}{4} dr^2$$

 λ : Factor determined by supporting method of ball screws Both ends supported $\lambda = \pi$ λ =3.927 One end fixed other end supported

 $\lambda = 4.730$

One end fixed other end free $\lambda = 1.875$ (2) Dm · N value (Perpendicular lines to permissible oper-

ating speed) The critical speed is also limited by Dm . N value that is the limit of the peripheral speed of a ball screw. Select a proper load value on the "Both ends fixed"

 $Dm \cdot N \leq 70,000$

scale.

Where Dm : Ball circle dia. (BCD) N : Number of revolutions (rpm)

Both ends fixed

(3) Parallel lines to the permissible operating speed represent the maximum length of screw shafts that can be manufactured in the standard operation for the nominal screw shaft outside diameter. As the screw shaft length is limited by the grade, refer to

Fig. 5 (Page 8).

4. DESIGN OF SCREW SHAFTS

4.6 Hints on Designing a Screw Shaft

(1) Mounting

When mounting a ball screw, it is not advisable to select such a construction that the screw shaft has to be disconnected from the nut. If the screw shaft is disconnected from the nut, the steel ball may come off, the nut position accuracy and preload amount may fluctuate and the steel ball circulating part may be broken. When it is unavoidably necessary to employ such a construction, supply us with a part mountable between the screw shaft and the nut. We will fit the part to the ball screw in out factory before shipment.

When disconnecting the screw shaft from the nut in an unavoidable case, use a sleeve as shown in Fig. 9 to disconnect the screw shaft with the steel ball housed in the nut. In this case, the sleeve outside diameter should be less than the screw shaft root diameter by 0.2 - 0.4mm (refer to the dimension table).

Fig. 9 Nut removing sleeve

(2) Configuration of screw shaft end

When designing a configuration for the screw shaft end, reduce the diameter of one end of the shaft to less than the screw shaft root diameter (refer to the dimension table.) and completely thread to the shaft end. Assembling of the return guide type ball screw is structurally impossible.

(3) Treatment of screw shaft end

When it is necessary to dowel the screw shaft after it is received, specify the position and size of the dowel pin. The product will be shipped with the specified portion unhardened for ease of post-treatment.

5. DESIGN OF NUTS

5.1 Structure of nut

The circuit system of ball screw is divided into "outer side circuit system" and "internal side circuit system". Outer side circuit system: tube type, return guide type Internal side circuit system: deflector type, end deflector type

(1) Tube type

The steel balls are picked up at the tip of U-shaped tube and rotate inside tube, then return back to screw grove.

Feature: Available for short to long lead

(2) Return guide type

The steel balls are picked up at the tip of deflector which is put inside nut and rotate through return guide, then come back to screw groove.

Feature: Available for short lead

deflector located opposite side.

(4) End deflector type

(3) Deflector type

The steel balls rotate through the deflector which is put inside nut. The steel balls circulate in just one lead.

Feature: Available for compact size nut diameter Good balance of rotation

Fig. 12-b End deflector type

through hole of nut and return back to screw groove via

The steel balls circulate through the end deflector which is put inside both end of the nut. The steel balls rotate inside

Feature: Available for high speed application Suitable for demand of low-sound rotation

Fig. 11-b Return guide type

5. DESIGN OF NUTS

5.2 Hints of Designing the Nut Associated Parts

(1) Unbalanced load

A ball screw is designed to work most effectively when load to the steel ball that rolls between the screw shaft and nut is uniformly distributed. If unbalanced load is applied to the nut, concentrated load is applied to some steel balls, adversely affecting the operating performance and life. So, special care should be taken to the design and assembly of equipment.

(2) Mounting direction of return guide type nut A return guide type ball screw should be mounted so that the return guide comes to the upside because of the construction of the steel ball circulating part. As a result, smooth rotation can be obtained.

6. DESIGN FOR ACCURACY

6.1 Rigidity of Feed Screw System

When accurate positioning is required for an automatic control machine or precision instrument incorporating a feed mechanism, the axial rigidity of each component of the feed screw system should be thoroughly examined.

6.1.1 Axial rigidity of feed screw system

(1) Axial rigidity of feed screw system: KT

The axial rigidity of the feed screw system can be obtained from the following equation.

$$K_{T} = \frac{Fa}{\delta}$$
$$\frac{1}{K_{T}} = \frac{1}{K_{S}} + \frac{1}{K_{N}} + \frac{1}{K_{B}} + \frac{1}{K_{H}}$$

- Where KT: Axial rigidity of feed screw system $(N/\mu m)$
 - Fa: Axial load to feed screw system (N)
 - δ : Axial elastic displacement of feed screw system (μ m) Ks: Axial rigidity of screw shaft (N/ μ m)

 - KN: Axial rigidity of nut $(N/\mu m)$
 - KB: Axial rigidity of support bearing (N/ μ m) Ku: Axial rigidity of nut and bearing mount
 - $(N/\mu m)$

(2) Axial rigidity of screw shaft: Ks(a) When "Both ends fixed" supporting method is not used:

$$K_{s} = \frac{A \cdot E}{Lz} \times 10^{-3}$$

Where Ks: Axial rigidity of screw shaft (N/ μ m) A: Sectional area of screw shaft (mm²)

$$A = \frac{\pi}{4} dr^{2}$$

- dr: Screw shaft root diameter (mm) (See Dimension Table)
- E : Modulus of longitudinal elasticity $(2.06 \times 10^{5} \text{N/mm}^{2})$
- Lz: Distance between loading points (mm)

Fig. 15 When "Both ends fixed" supporting method is not used:

(b) When "Both ends fixed" supporting method is used:

$$K_{s} = \frac{A \cdot E \cdot L}{Lz (L - Lz)} \times 10^{-3}$$

Where Ks : Axial rigidity of screw shaft (N/ μ m) L : Distance between supports (mm)

Fig. 16 When "Both ends fixed" supporting method is used:

(Note) Screw shaft displacement by axial load

(a) When "Both ends fixed" supporting method is used:

$$\delta_{L} = \frac{Fa}{Ks} = \frac{Fa \cdot Lz}{A \cdot E} \times 10^{3}$$

Where δ L: Displacement by axial load (μ m) (b) When "Both ends fixed" supporting method is not used:

$$\delta_{L} = \frac{Fa}{Ks} = \frac{Fa}{A \cdot E} (1 - \frac{Lz}{L})Lz \times 10^{3}$$

Where δ_{\perp} : Displacement by axial load (μ m)

When "Both ends fixed" supporting method is used, the axial displacement maximizes at position Lz=L/2.

$$\left(\delta_{L}=\frac{Fa\cdot L}{4A\cdot E}\times 10^{3}\right)$$

Consequently, the maximum axial displacement for a case of "Both ends fixed" supporting method is reduced to 1/4 as compared with a case other than "Both ends fixed" supporting method.

6. DESIGN FOR ACCURACY

(3) Rigidity of nut: KN

(a) Rigidity of clearance ball screw Dimension Table gives theoretical rigidity K obtained from elastic displacement between the thread groove and steel ball when axial load equivalent to 30% of basic dynamic load rating Ca is applied. Taking into consideration the nut, use of 80% of each value shown in the Table as a general rule. When axial load Fa differs from 0.3Ca, rigidity K^N can be obtained from the following equation.

$$K_{\rm N} = 0.8 \times K \left(\frac{Fa}{0.3Ca}\right)^{1/3} (N/\mu m)$$

Where K : Rigidity in Dimension Table $(N/\mu m)$ Fa : Axial load (N)Ca : Basic dynamic load rating (N)

(b) Rigidity of preloaded ball screw

Dimension Table gives theoretical rigidity K obtained from elastic displacement between the thread groove and steel ball when axial load equivalent to 10% (5% for oversize ball preloading type) of basic dynamic load rating is applied. Taking into consideration the nut, use of 80% of each value shown in the Table as a general rule. When axial load Fao differs from 0.1Ca (0.05Ca), rigidity K_N can be obtained from the following equation.

$$K_N = 0.8 \times K \left(\frac{Fao}{\epsilon Ca}\right)^{-1/3} (N/\mu m)$$

Where K : Rigidity in Dimension Table (N/ μ m)

- Fao : Preload (N)
- ε : Basic coefficient for calculating rigidity ε =0.10

 ε =0.05 (Oversize ball preload)

(4) Rigidity of support bearing: KB

Rigidity is determined according to the type of bearing used (ball bearing, roller bearing), preload amount, etc. Rigidity K_B with roller bearing preloaded is obtained from the following equation.

$$K_B \rightleftharpoons \frac{3Fao}{\delta ao} (N/\mu m)$$

Where Fa₀ : Preload (N) δ a₀: Axial elastic displacement for preload (μ m) Provided 0 < Axial external load \leq 3Fa₀

(a) Axial elastic displacement of thrust angular ball bearing (for supporting ball screw) and angular ball bearing

$$\delta a = \frac{2}{\sin \alpha} \left(\frac{Q^2}{Da}\right)^{1/3} \quad Q = \frac{Fa}{Z \cdot \sin \alpha}$$

(b) Axial elastic displacement of tapered roller bearing

$$\delta a = \frac{0.6}{\sin \alpha} \times \frac{Q^{0.9}}{\ell a^{0.8}} \qquad Q = \frac{Fa}{Z \cdot \sin \alpha}$$

(c) Axial elastic displacement of thrust ball bearing

$$\delta a = 2.4 \left(\frac{Q^2}{Da} \right)^{1/3} \qquad Q = \frac{Fa}{Z}$$

Where δa : Axial elastic displacement (μ m)

- α : Contact angle
- Q : Load per rolling element (N)
- Da : Steel ball diameter (mm)
- ℓa : Effective contact length of roller (mm)
- Fa : Axial load (N)
- Z : Number of rolling element
- (5) Rigidity of mounting part of nut and bearing: K_H When designing a feed unit, try to provide high rigidity

for the mounting part.

6.1.2 Torsional strength of screw shaft

Angle of torsion that will be produced by twisting moment of the screw shaft can be obtained from the following equation.

$$\theta = \frac{32\mathrm{T}\cdot\mathrm{L}}{\pi\cdot\mathrm{G}\cdot\mathrm{d}\mathrm{r}^4} \times \frac{360}{2\pi} = 7.21 \times 10^{-2} \frac{\mathrm{T}\cdot\mathrm{L}}{\mathrm{d}\mathrm{r}^4}$$

Where θ : Angle of torsion (degree)

- T : Twisting moment ($N \cdot mm$)
- L : Distance between torsional points (mm)
- G : Modulus of traverse elasticity (7.9 × 10⁴N/mm)
- dr : Screw shaft root diameter (mm) (See Dimension Table.)

Lag Δ of axial movement by angle of torsion can be obtained from the following equation:

$$\Delta = \ell \times \frac{\theta}{360} \times 10^3 \ (\mu \,\mathrm{m})$$

Where ℓ : Lead of ball screw (mm)

6.1.3 Preload of Ball Screws

When extremely accurate positioning is required, it is usual to preload the ball screw to increase the rigidity so that elastic displacement to the axial load may be minimized with the axial clearance of the ball screw zeroed.

(1) Preloading

- (a) Double nut preloading (Spacer preloading)
 - In this type, a spacer is inserted between two nuts to achieve correct preload. There are two methods of preloading. One method is called "Tension preloading" by which a thick spacer with a thickness equivalent to the amount of preload is inserted between the nuts to obtain correct preload as shown in Fig. 17.

Sankyo precision ball screws use the "Tension preloading" as a standard method of preloading.

Another method of preloading is to insert a thin spacer with a thickness equivalent to the amount of preload between the nuts to obtain correct preload. It is called "Compression preloading".

- (b) Single nut preloading (Oversize ball preloading)
- In this type, preload is applied by using one nut. As shown in Fig. 18, a steel ball (Oversize ball) which is slightly larger than the clearance in the thread groove is inserted and brought into contact at four points to attain correct preload.

In order to improve the working efficiency, a spacer ball (1:1) is generally used. (Fig. 19)

Fig. 19 Spacer ball

(c) Single nut preloading (Offset ball preloading) In this type, preload is applied by using one nut. As shown in Fig. 20, the lead at the center of the nut is enlarged by an amount of preload a for preloading.

Fig. 20 Offset lead preloading

(2) Axial elastic deformation

When a ball screw receives axial load, the steel ball and the thread groove surface will deform. The relationship between the amount of axial elastic deformation δa and the axial load Fa is calculated from Herz's point contact theory similarly to ball bearings.

δ

 (a) Axial elastic deformation of single nut (Non-preload): δ a

$$a = \frac{2.6}{\sin \alpha} \left(\frac{Q^2}{Da}\right)^{1/3} \times \xi \ (\mu \text{ m})$$

Where α : Contact angle of steel ball with thread groove (45°)

- Da: Steel ball diameter (mm)
- Q: Load per steel ball (N)
- $Q=Fa/Z \cdot \sin \alpha$
- Z : Number of steel balls
- ξ : Coefficient for accuracy and construction

6. DESIGN FOR ACCURACY

(b) Axial elastic deformation of preloaded ball screw

As shown in Fig. 21, preload Fa0 is applied to nuts A and B, both nuts will be elastically deformed up to point X. When external force Fa is exerted in this state, nut A shifts from point X to point X1 and nut B from point X to point X2. (Fig. 22)

Assuming that proportional constant is k, formula $\delta a \propto Fa^{23}$ gives the following equation:

$$\delta a_0 = \mathbf{k} \cdot \mathbf{F} a_0^{2/3}$$

The amount of deformation of nuts A and B is as follows:

$$\delta_{\rm A} = \mathbf{k} \cdot \mathbf{F}_{\rm A}^{2/3}$$
$$\delta_{\rm B} = \mathbf{k} \cdot \mathbf{F}_{\rm B}^{2/3}$$

Because the amount of deformation of nut A by the external force Fa is equal to that of nut B, the following equation is formed:

$$\delta_{A} - \delta_{a0} = \delta_{a0} - \delta_{B}$$

In addition, the external force applied to nut A and B is Fa alone. Therefore,

$$F_A - F_B = F_a$$

According as F_A increases, the external force applied to nut B is reduced by the absorption of nut A until $\delta_B=0$. As a result, where $\delta_B=0$

$$k \cdot Fa^{2/3} - k \cdot Fao^{2/3} = k \cdot Fao^{2/3}$$
$$Fa^{2/3} = 2Fao^{2/3}$$
$$Fa = \sqrt{8} Fao \rightleftharpoons 3Fao$$

Also, from the equatio $\delta_A - \delta_{a0} = \delta_{a0}$, the following equation is formed:

$$\delta a_0 = \frac{1}{2} \delta A$$

Consequently, when axial load is three times as much as the amount of preload, the amount of deformation on the preloaded ball screw becomes half as much as that of a nonpreloaded ball screw, while the rigidity doubles. (See Fig. 23.)

$$K = \frac{Fa}{\delta ao} = \frac{3Fao}{0.5\,\delta a}$$

Where K : Rigidity $(N/\mu m)$

- Fa : Axial load (N)
- δ ao: Axial elastic deformation of preloaded ball screw (μ m)
- Fao: Preload (N)
- δa : Axial elastic deformation of non-preload ball screw (μ m)

Fig. 23 Axial elastic deformation curves

(3) Preload setting

Recommendable preload is about 1/3 of the maximum axial load. Since excessive preload results in heating and adversely affects the service life, set the maximum preload at 10% of basic dynamic load rating Ca as a general rule.

Table 6 shows standard preload.

Table 6. Standard Preload

| | 일본 이 것 같은 것 같은 것 같은 것 같이 많은 것이 | Unit. N |
|---------------------|--------------------------------|--------------------------|
| Classi- fication | Light preload | Medium and heavy preload |
| Preload | Less than 0.05Ca | Over 0.05 to 0.10Ca |

7. DESIGN OF RATED LIFE

7.1 Life of Ball Screw

The life of a ball screw is classified into fatigue life caused by flaking and wear life resulting in the deterioration of accuracy.

7.2 Fatigue Life

The fatigue life can be estimated by using the basic rated dynamic load as in the case of rolling bearings.

7.2.1 Basic rated dynamic load: Ca

The basic rated dynamic load is an axial load at which, when a group of the same ball screws are revolved under the same condition, more than 90% of these ball screws can reach the rated life of 1,000,000 revolutions without flading. The basic rated dynamic load is given in Dimension Tables.

7.2.2 Fatigue Life

(1) Calculating the life

Fatigue life is generally expressed by a total number of revolutions, but it is sometimes expressed by total revolution time or total travel distance. Fatigue life can be calculated from the following formula:

$$L = \left(\frac{Ca}{Fa \cdot fw}\right)^{3} \times 10^{6}$$

$$Lt = \frac{L}{60n}$$

$$Ls = \frac{L \cdot R}{10^{6}}$$

| Where | L : Rated fatigue life | (rev) |
|-------|-----------------------------------|----------|
| | Lt : Life time | (hr) |
| | Ls : Life in travel distance (km) | |
| | Ca: Basic rated dynamic load | (N) |
| | Fa : Axial load | (N) |
| | n : Number of revolutions | (rpm) |
| | r : Lead | (mm) |
| | fw: Load factor | |
| | (Classified by operating con | ditions) |
| | Shockless smooth operation | 1.0- |

| Vibratory operation | 1.5-3.0 |
|----------------------------|---------|
| Ordinary operation | 1.2-1.5 |
| Shockless smooth operation | 1.0-1.2 |

(2) Average load

 (a) When load and number of revolutions are classified by stages (Fig. 24):

| Axial load (N) | Number of revolu- tions (rpm) | Operating time or operating time ratio |
|-------------------|----------------------------------|---|
| F1 | nı | fı |
| F2 | n2 | f2 |
| 1 | : | : |
| Fn | nn | fn |

Average load Fm can be calculated from the following formula:

$$Fm = \left(\frac{F_{13} \cdot n_1 \cdot t_{11} + F_{23} \cdot n_2 \cdot t_2 + \dots + F_{n3} \cdot n_n \cdot t_n}{n_1 \cdot t_1 + n_2 \cdot t_2 + \dots + n_n \cdot t_n}\right)^{1/3}(N)$$

Average number of revolutions Nm can be calcurated from the following formula:

$$Nm = \frac{n_1 \cdot t_1 + n_2 \cdot t_2 + \dots + n_n \cdot t_n}{t_1 + t_2 + \dots + t_n} (rpm)$$

(b) When load varies almost linearly (Fig. 25): Average load Fm can be proximately calculated from the following formula:

$$Fm = \frac{1}{3}(Fmin + 2Fmax)$$
 (N)

Where F min : Minimum axial load (N) F max : Maximum axial load (N)

Fig. 25 Monotonouly varying load

(c) When load varies drawing a since curve (Fig. 26).:

Average load Fm can be calculated from the following formula: Fm ≒ 0.65Fmax (N) for (a) in Fig. 26

Fm \Rightarrow 0.75Fmax (N) for (b) in Fig. 26

Fig. 26 Varying load drawing a sine curve

7. DESIGN OF RATED LIFE

7.2.3 Standard Life Time

If you request a long fatigue life unnecessarily when selecting a ball screw, you would get a large ball screw, resulting in poor economy. Some case examples of standard life requirements are given below for reference.

| Machine tools | 20,000 | hours |
|-----------------------------|--------|-------|
| Industrial machinery | 10,000 | hours |
| Automated control equipment | 15,000 | hours |
| Measuring instruments | 15,000 | hours |

7.3 Permissible Load to Thread Groove

Even when a ball screw is not frequently used or is operated at low speed or other reasonable conditions meeting the fatigue life, it is necessary to select a ball screw so that the maximum axial load may be lower than the basic rated static load.

7.3.1 Basic Rated Static Load: Coa

The basic rated static load is an axial static load under which the sum of permanent deformations of the following three factors may be equal to 0.01% of the steel ball diameter.

- Contact area of thread groove of screw shaft receiving the maximum stress.
- Contact area of thread groove of nut receiving the maximum stress.
- · Steel ball receiving the maximum stress.

7.3.2 Permissible Load

The maximum permissible load Fmax can be calculated from the following formula:

Fmax = Coa/fs (N)

Where Coa : Basic rated static load (N)

fs : Safety factor

(Classified by operating conditions)

| Ordinary operation Vibratory operation | 1 - 2 - | 23 |
|---|---------|----|
|---|---------|----|

7.4 Materials and Harness

7.4.1 Standard Materials

Table 7. Materials and Hardness

| Part name | Material | Heat-treatment | Hardness |
|--------------------|----------|----------------|----------|
| Screw shaft Nut | SCM415H | Carburizing | HRC58-62 |

*Ball screws made of special materials such as stainless steel for specific environment applications (SUS440C, SUS630) are manufactured upon order. We accept an order of surface-treatment.

7.4.2 Hardness Factor

When some material other than the standard materials shown in Table 9 with surface hardness of less than H_RC58 is used, it is necessary to correct the basic rated dynamic load (Ca) and basic rated static load (Coa). Correct Ca and Coa values shown in Dimension Table by using the following formula:

$$Ca' = f_H \cdot Ca$$
 (N)

 $Coa' = f_{H'} \cdot Coa$ (N)

Where f_H : Hardness factor f_H : Static hardness factor

8. DRIVING TORQUE

8.1 Torque of Ball Screw

(1) Normal operation

When rotation is converted into linear motion (Normal operation), the torque can be obtained from the following formual:

$$Ta = \frac{Fa \cdot R}{2 \pi \cdot \eta_1} \times 10^{-3}$$

Where Ta : Normal operation torque (N•m)

(2) Reverse operation

When linear motion is converted into rotation (Reverse operation), the torque can be obtained from the following formula:

$$Tb = \frac{Fa \cdot R \cdot \eta_2}{2 \pi} \times 10^{-3}$$

Where Tb: Reverse operation torque(N•m) η_2 : Reverse efficiency (0.85 - 0.9)

(3) Preload torque

Basic torque of preloaded ball screw can be obtained from the following formula:

$$T_{\rm P} = 0.05 \, (\tan\beta) \frac{10.5 \, \text{Fao} \cdot \text{R}}{2 \, \pi} \times 10^{-3}$$

Where Tp : Normal operation torque (N·m) Fao: Preload (N) β : Lead angle (deg)

8.2 Driving Torque of motor

(1) Driving torque at constant speed

Torque T1 required for driving the ball screw at constant speed against the external load can be obtained from the following formula:

$$T_1 = (T_a + T_P + T_B) \times \frac{N_1}{N_2}$$

Where Ta : Driving torque at constant speed

Fa=F+ μ •W (N)••In case of horizontal position

- F : Cutting force in screw shaft direction (N)
- : Frictional coefficient of sliding surface
- W : Weight of table and work (N)
- (Weight of table+Weight of work) TB : Frictional torque of support bearing (N•m)
- N1: Number of teeth of gear 1
- N2: Number of teeth of gear 2

(2) Driving torque at acceleration

When the ball screw is driven with accelerated velocity against the axial load, the maximum load is required. Torque required at this time can be obtained from the following formula:

$$T_2 = T_1 + J \cdot \dot{\omega}$$

$$J = J_M + J_{G1} + \left(\frac{N_1}{N_2}\right)^2 \left(J_{G2} + J_S + m \left(\frac{R}{2\pi}\right)^2 \times 10^6\right)$$

Where T2: Maximum driving torque at acceleration (N•m)

- ω : Angular acceleration of motor (rad/sec²)
- Moment of inertia to motor (kg m2) J :
- J_M : Moment of inertia to motor (kg·m²) J_{G1} : Moment of inertia of gear 1 (kg·m²)
- J_{G2}: Moment of inertia of gear 2 (kg•m²) Js : Moment of inertia of screw shaft (kg•m²)
- m: Mass of transfer material (kg)

(Note) Moment of inertia of cylindrical components

$$J = m(\frac{D^2}{8}) \times 10^6 \ (kg \cdot m^2)$$

Where m: Mass of cylinder (kg)

D: Diameter of cylinder (mm)

9. LUBRICATION AND DUST-PROOFING

9.1 Lubrication

Ball screws feature "No seizure under no lubricant" However a proper amount of lubridcant is required from the viewpoint of the life expectancy and machine efficiency. Generally, grease and oil are used as lubricants.

For lubrication with grease, lithium soap-based grease is used and for lubrication with oil, oil of ISO grade 32 - 100 is used.

Usually, lubricants with low base oil viscosity are recommended for high-speed, low-temperature and light load applications. Lubricants with high base oil viscosity are recommended for sliding, low-speed, high-temperature and high load applications. Lubricants, Inspection Period and Supply are listed in table 8.

Table 8. List of recommended lubricants

| Lubricant | Inspection period | Check point | Supply |
|-----------|----------------------|-------------------------|--|
| Grease | Initial 2 — 3 months | Dirt and foreign matter | Supply (proper amount according to inspection results) every year. Wipe off old grease before supplying new grease. |
| Oil | Every week | Oil quantity and dirt | Supply new oil at the time of every inspection. |

9.2 Dust-proofing

Similar to a roller bearing, if dust or foreign matter gets into the ball nut of a ball screw, it may cause damage to the thread groove surface or may hasten the wear of such parts, resulting in failure of the circulating mechanism and causing the ball screw to be inoperative. When entry of dust or foreign matter from the outside is anticipated, completely protect the screw shaft with bellows or a screw cover as shown in Fig. 29.

If it is impossible to mount these covers due to the design involved, fit seals (Fig. 30) at both ends of the ball nut for dust-proofing. However, the dust-proofing effect has its limit.

Sankyo Precision ball screws are provided with seals upon request.

10. GEOMETRY OF NUTS

Type: DC See Pages 26 and 27.

RETURN GUIDE TYPE SINGLE FLANGE SINGLE NUT (Non-preloaded)

Simplest type using a single nut. For use in slight axial clearance.

Type: DP See Pages 28 and 29.

RETURN GUIDE TYPE SINGLE FLANGE SINGLE NUT (Over-size ball preloaded)

Designed to preload with a single nut. Steel balls whose diameter is slightly larger than clearance between screw shaft and thread groove of nut are put in the nut and preloaded. The ratio of load balls to spacer balls used there is 1:1 Suitable for light preload (See Page 17.)

Type: DD See Pages 30 and 31.

RETURN GUIDE TYPE SINGLE FLANGE DOUBLE NUT (Spacer preloaded)

Designed to preload with two nuts. A spacer with thickness equivalent to amount of preload is put between these two nuts and preloaded as prescribed. Suitable for medium preload. (See Page 17.)

Type: TCS See Pages 32 and 33.

TUBULAR TYPE SMALL LEAD, SINGLE FLANGE SINGLE NUT (Non-preloaded)

Simplest type using a single nut. For use in slight axial clearance.

Type: TPS See Pages 34 and 35.

TUBULAR TYPE SMALL LEAD, SINGLE FLANGE SINGLE NUT (Over-size ball preloaded)

Designed to preload with a single nut. Steel balls whose diameter is slightly larger than clearance between screw shaft and thread groove of nut are put in the nut an preloaded. The ratio of load balls to spacer balls used there is 1:1. Suitable for light preload (See Page 17.)

Type: TDS See Pages 36 and 37.

Remarks

(1) Flange configuration As shown in Fig. on the left side, two flange configurations R type (standard) and H type are available. Select the correct one according to the space for the nut mouting portion.

(2) Seal

The standard type is not provided with a seal. However, it is also possible to attach seals to both ends of the nut.

(3) Stiffness

Stiffness shown in Table below is a theoretical value obtained from elastic deformation between the thread groove and steel ball when an axial load is equivalent to 30% of basic rated dynamic load (Ca) is applied. It is recommended to use 80% of each value given in Table below.

Remarks

(1) Flange configuration As shown in Fig. on the left side, two flange configurations R type (standard) and H type are available. Select the correct one according to the space for the nut mouting portion.

(2) Seal

The standard type is not provided with a seal. However, it is also possible to attach seals to both ends of the nut.

(3) Basic rated load

Since sthe ratio of load balls to spacer balls put in the nut is 1:1, the basic rated load of this type differs from that of the other types.

(4) Stiffness

Stiffness shown in Table below is a theoretical value obtained from elastic deformation between the thread groove and steel ball when an axial load is applied, assuming that the preload is 5% of basic rated dynamic load (Ca). It is recommended to use 80% of each value given in Table below.

(1) Flange configuration

As shown in Fig. on the left side, R type (standard) and S type for shaft outside diameters of less than 14mm and R type (standard) and C type for shaft outside diameters of more than 16mm are available. Select the correct one according to the space for the nut mounting portion. The R type with shaft outside diameters of less than 14mm is provided with four mounting bolt holes (4 x 90°).

(2) Seal

For the type with a seal, the nut length is longer than of the type without a seal by M. For the type with shaft outside diameters less than 16mm, the nut has the same length.

(3) Stiffness

Stiffness shown in Table below is a theoretical value obtained from elastic deformation between the thread groove and steel ball when an axial load equivalent to 30% of basic rated dynamic load (Ca) is applied. It is recommended to use 80% of each value given in Table below.

As shown in Fig. on the left side, R type (standard) and S type for shaft outside diameters of less than 14mm and R type (standard) and C type for shaft outside diameters of more than 16mm are available. Select the correct one according to the space for the nut mounting portion. The R type with shaft outside diameters of less than 14mm is provided with four mounting bolt holes ($4 \times 90_{\circ}$).

(2) Seal

For the type with a seal, the nut length is longer than of the type without a seal by M. For the type with shaft outside diameters less than 16mm, the nut has the same length.

(3) Basic rated load

Since the ratio of load balls to spacer balls put in the nut is 1:1, the basic rated load of this type differs from that of the other types.

(4) Stiffness

Stiffness shown in Table below is a theoretical value obtained from elastic deformation between the thread groove and steel ball when an axial load equivalent to 30% of basic rated dynamic load (Ca) is applied. It is recommended to use 80% of each value given in Table below.

(1) Flange configuration As shown in Fig. on the left side, two flange configura-tions R type (standard) and C type are available. Select the correct one according to the space for the nut mounting portion.

(2) Seal

For the type with a seal, the nut length is longer than of the type without a seal by M.

(3) Stiffness

Stiffness shown in Table below is a theoretical value obtained from elastic deformation between the thread groove and steel ball when an axial load is applied, assuming that the preload is 10% of basic rated dynamic load (Ca). It is recommended to use 80% of each value given in Table below.

(1) Flange configuration As shown in Fig. on the left side, two flange configurations R type (standard) and S type are available. Select the correct one according to the space for the nut mounting portion.

(2) Seal

For the type with a seal, the nut length is longer than of the type without a seal by M.

(3) Basic rated load

Since the ratio of load balls to spacer balls put in the nut is 1:1, the basic rated load of this type differs from that of non-preloaded.

(4) Stiffness

Stiffness shown in Table below is a theoretical value obtained from elastic deformation between the thread groove and steel ball when an axial load is applied, assuming that the preload is 5% of basic rated dynamic load (Ca). It is recommended to use 80% of each value given in Table below.

(Specification & notice)

- (1) Accuracy Grade JIS C5
- (2) Axial Clearance under 0.005mm
- (3) Material Shaft & Nut: SCM415H

(4) The oil for preventing rust is put to the ballscrew when deliveried.

Please lubricate grease or oil by customer side when use the ballscrew.

Application Example: Measurement of Lead and Nut Assembly (PAT.)

14. HANDLING PRECAUTIONS FOR BALL SCREWS

As Ball Screws are precision parts, carefully handle them by referring to the following instructions:

Lubrication

1. Thoroughly check the lubricant condition before use.

Improper lubrication will shorten the service life of Ball Screw.

- 2. When lubricating grease is applied to Ball Screw, use the Ball Screw directly. However, if dust and chips accumulate on the surface of grease coating, clean it with pure kerosene or degrease, and then apply new lubricating grease of the same type as coated on the Ball Screw before use. When degreasing Ball Screw, avoid using organic solvent which may melt acrylic adhesives.
- 3. Check the grease 2 to 3 months after Ball Screw is used for the first time. If the grease is extremely dirty, wipe off old grease and apply a sufficient amount of new grease. Thereafter, check and replenish every year, but perform periodic check and maintenance according to operating conditions for the Ball Screw.

Handling

- 1. Never disassemble Ball Screw. Other wise, dust may enter it, resulting in an accient and degrading accuracy.
- 2. Avoid reassembling Ball Screw on the user side. Otherwise the function of the Ball Screw may be lost due to incorrect assembling. Send the Ball Screw to our company for repair and reassembly at your expense.
- 3. As Ball Screw or Nut may sometimes drop spontaneously, be careful not to get hurt. If Ball Screw drops, its function may be lost due to a damage to the circulating parts etc.

In this case, the Ball Screw should be checked by our company.

- Be sure to send it to our company for check and repair at your expense.
- 4. When Ball Screw drops, the circulating parts, shaft outside surface, ball groove, etc, may be flawed or scratched.

Operating Precautions

1. Use Ball Screw in a clean environment. Prevent dust and chips from entering Ball Screw by using a dustproof cover. Dust and chips which enter Ball Screw due to insufficient dustproofing may adversely affect the performance of the Ball Screw, causing to lock it or damage the circulating parts or sometimes drop the table.

2. For operating speed of Ball Screw, refer to "Permissible Operating Speed" given in Sankyo BALL SCREW CATALOG or specifications and drawings supplied by our company. If the permissible operating speed is exceeded during operation, the circulating parts may be damaged, some-

The permissible operating speed is exceeded during operation, the circulating parts may be damaged, sometimes resulting in a lock or an accidental drop of the table.

When Ball Screw is mounted on a vertical axis, it is recommended that safety nuts or drop prevention be provided. For details of a safety device, contact our company.

3. If Ball Screw Nut is overrun, the ball may drop, the circulating part may be damaged or the ball groove may dent, causing a malfunction.

Be careful not to overrun Ball Screw without fail.

If your Ball Screw is overrun, contact our company. We will check it or take proper countermeasures at your expense.

4. The operating temperature limit is usually set at less than 80 °C. Avoid operating Ball Screw at higher temperature than the temperature limit. Otherwise, the circulating parts and sealing parts may be damaged.

Storage

- 1. When storing Ball Screw, keep it in the original package supplied by our company. Do not unpack or tear the package except in case of need. Otherwise, dust may enter Ball Screw, resulting in resting and deterioration of the performance.
- 2. It is recommendable to store Ball Screw as follows;
 - (1) Place it horizontally in the original package supplied by our company.
 - (2) Put a sleeper on Ball Screw and place them horizontally in a clean place.
 - (3) Suspend Ball Screw in a clean place.
